Outline:

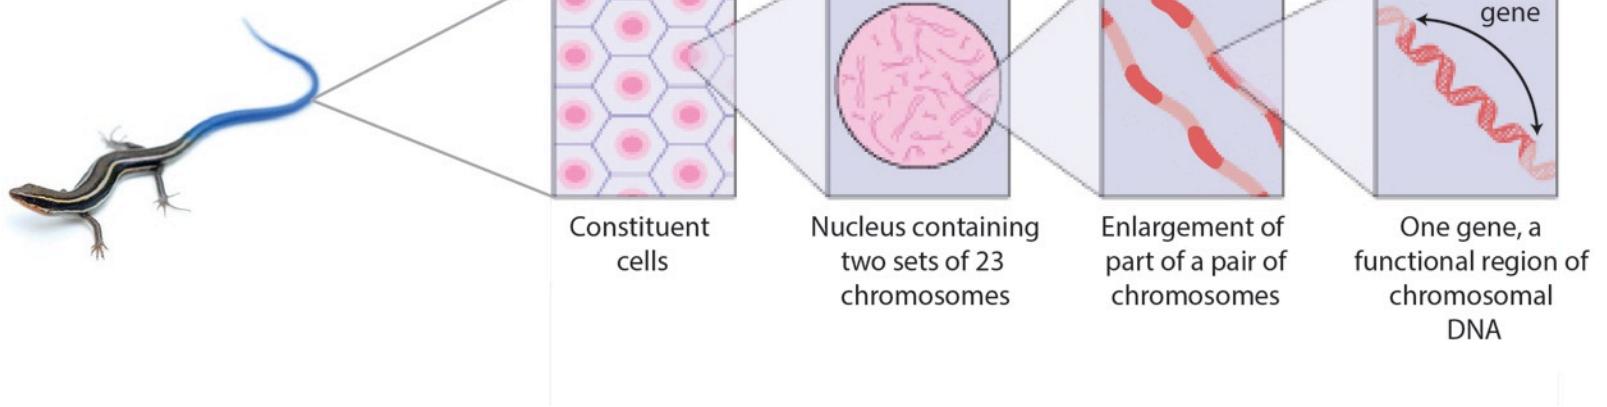

1. Sources of DNA in animals
2. The types of DNA data we collect:
 - Single nucleotide polymorphisms (SNPs)
 - Microsatellites
 - DNA sequence data
3. Visualization and interpretation of the data
 - Phylogenetic trees
 - Cluster assignment plots
4. Measuring genetic diversity:

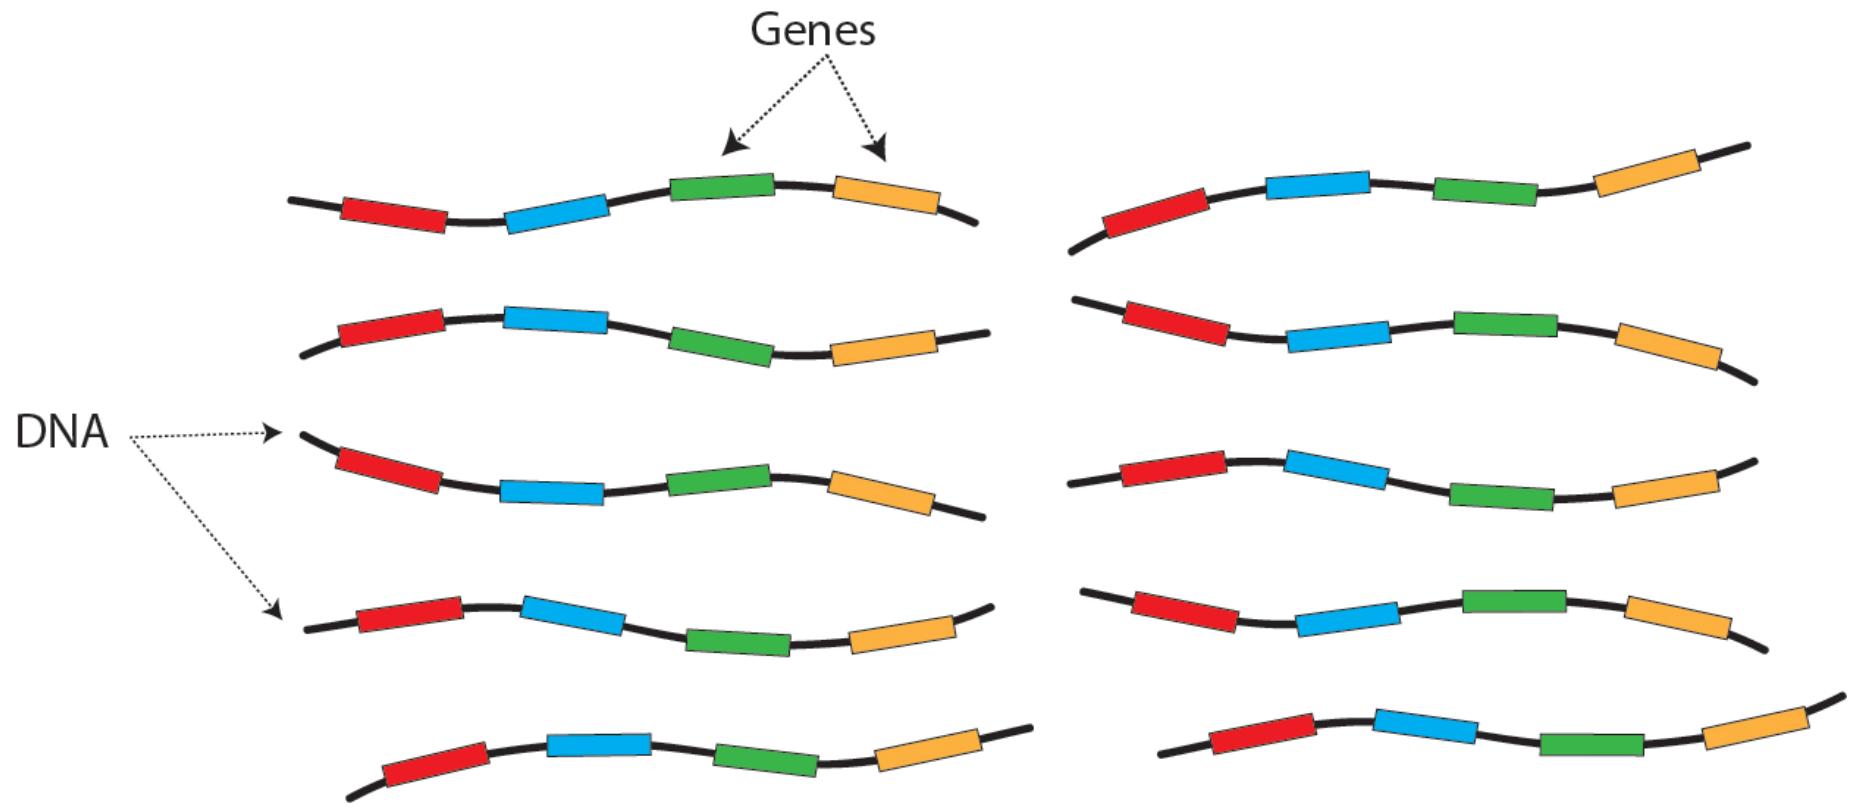

Case study: Conservation genetics of the California red-legged frog
Rana draytonii

Two main sources of DNA in animals:

- Nuclear DNA
 - Contained within the cell nucleus of eukaryotic organisms
 - Bi-parentally transmitted from parent to offspring
 - Undergoes recombination
- Mitochondrial DNA (mtDNA)
 - Located in organelles called mitochondria within cells
 - Derived from the circular genomes of the bacteria that were engulfed by the early ancestors of today's eukaryotic cells
 - Maternally inherited
 - No recombination

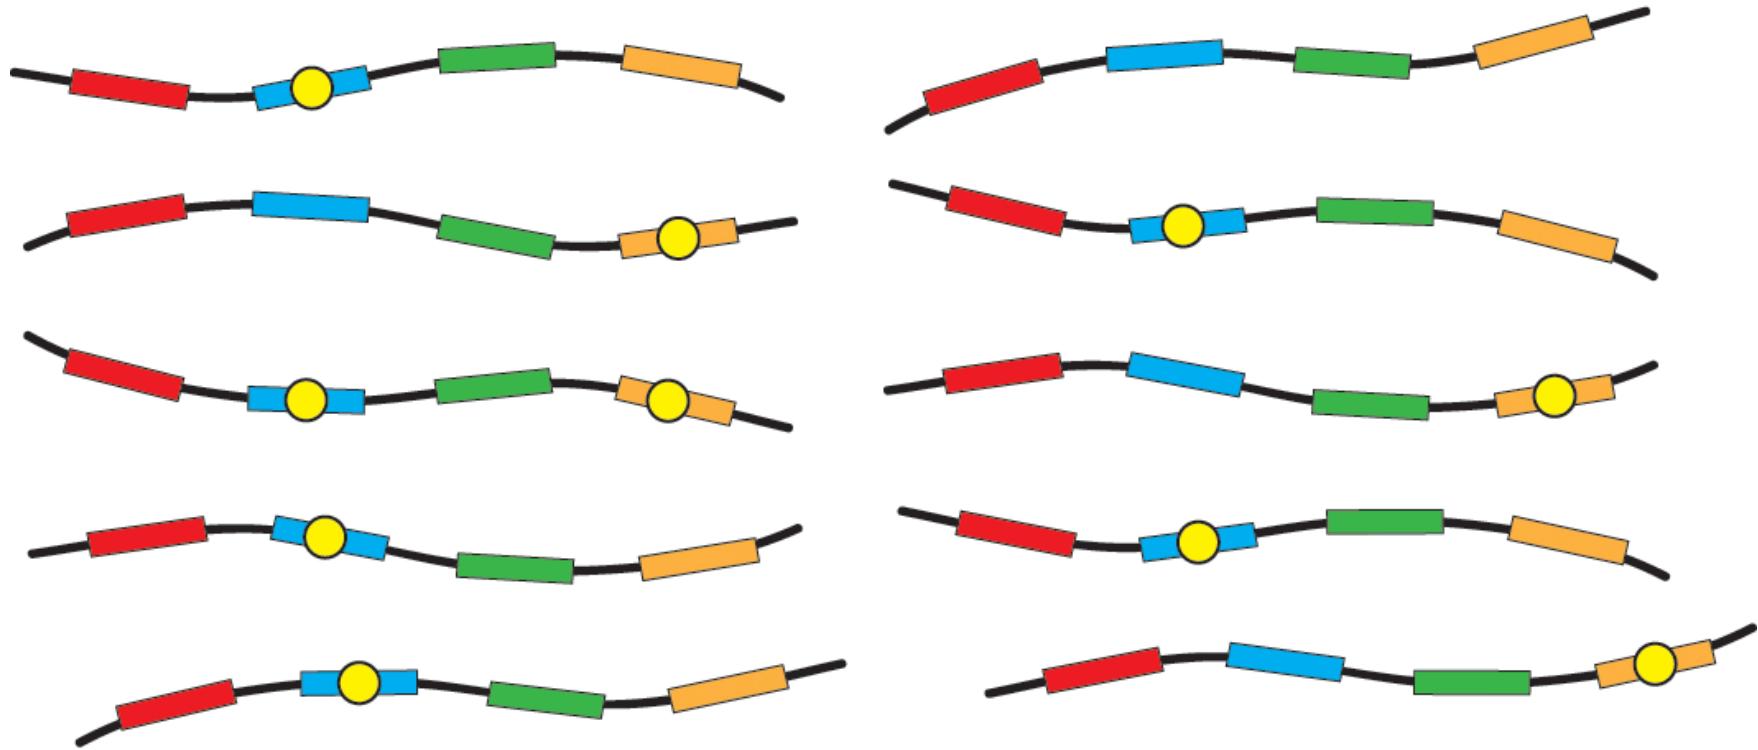

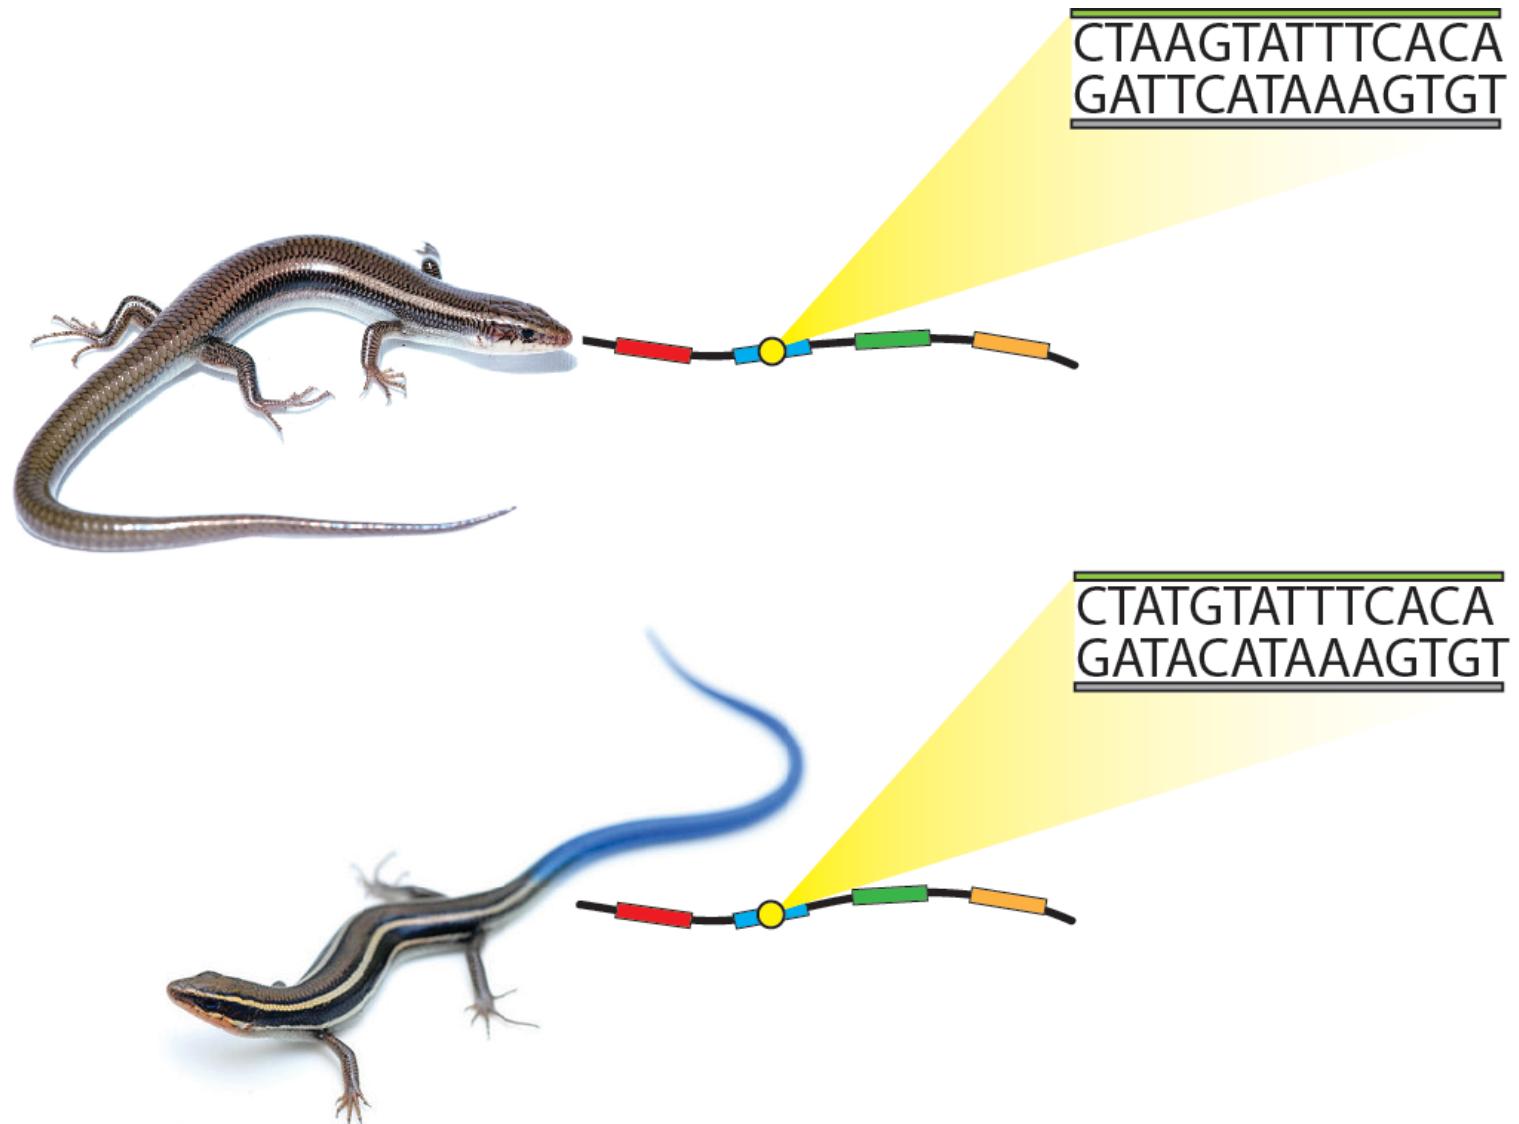

Genetic differences between organisms are evident in their DNA sequences.

Single Nucleotide Polymorphisms (SNPs)

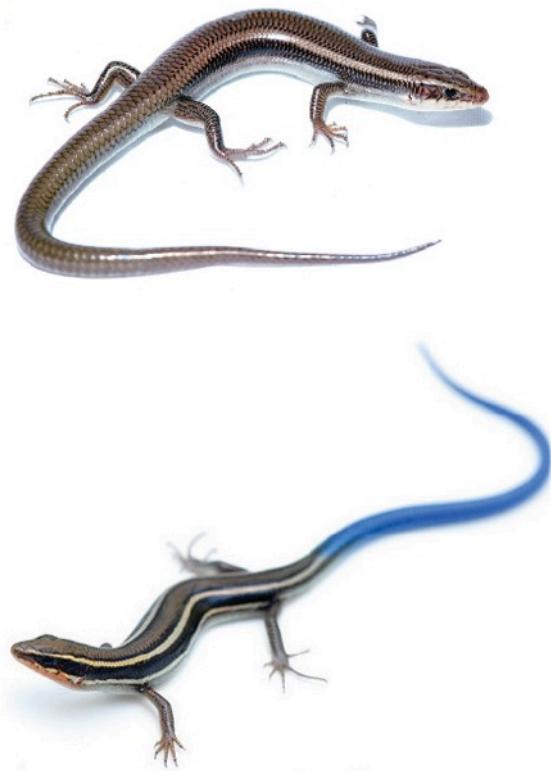

Many of the genetic differences are single nucleotide substitutions in the DNA sequence.

Here we have two short, double stranded DNA sequences taken from the same region of the genome in two different skinks.

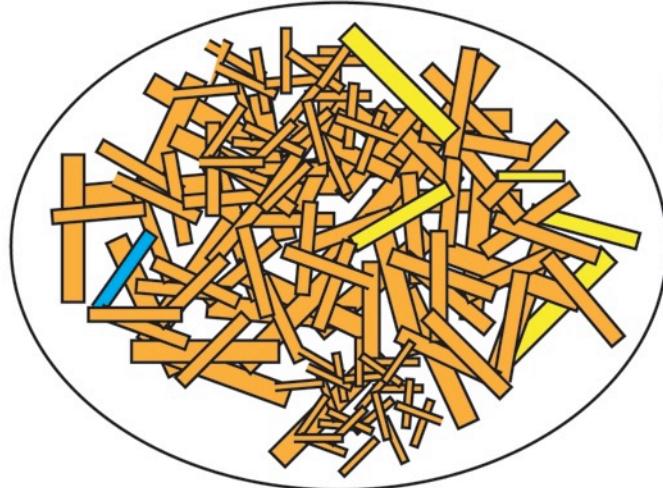

Keeping it simple, we'll just show one strand....

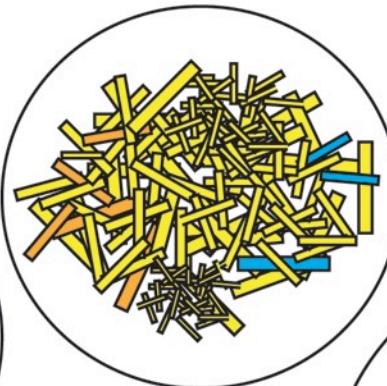

CTATGTATTTCACA
SNP
CTAAGTATTTCACA

The sequences are almost identical except for one nucleotide position.

Causes of decline...

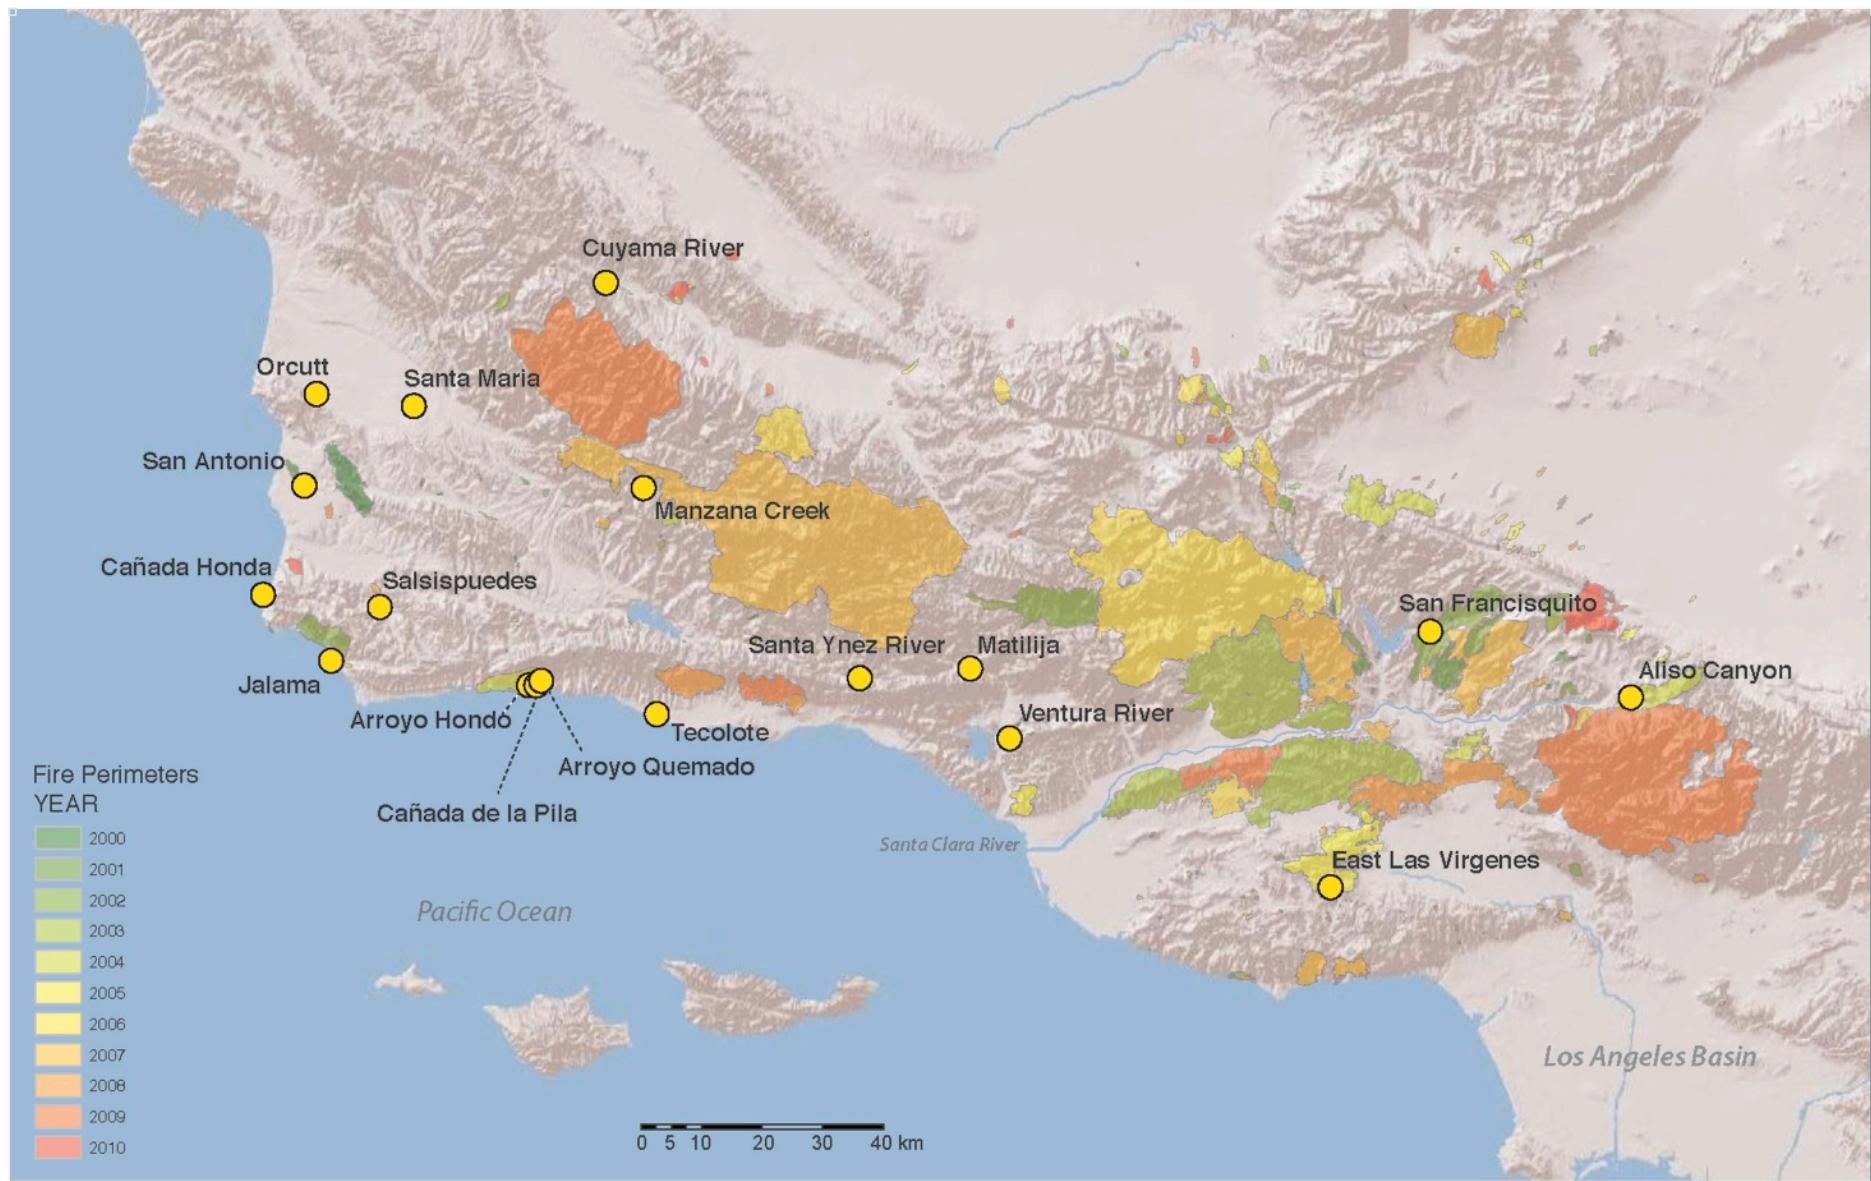

Why are marginal populations often evolutionarily unstable?

1. Insufficient genetic variation to respond to changes in selective regimes at the species boundary...
or
maladaptation to environments beyond the current species boundary.
2. Increased competition with other species.
3. Reduced gene flow with 'internal' populations.
4. Fragmented populations of smaller size.
5. Interactions between these and other variables.

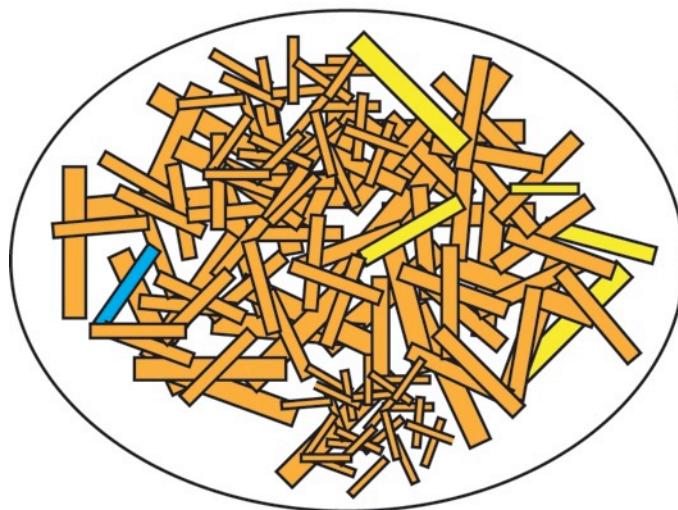

Some of our research questions:

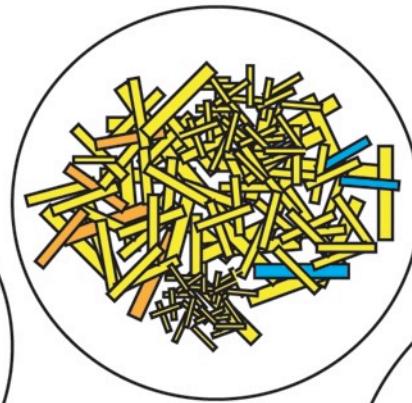

How are *R. draytonii* populations genetically structured across the landscape?

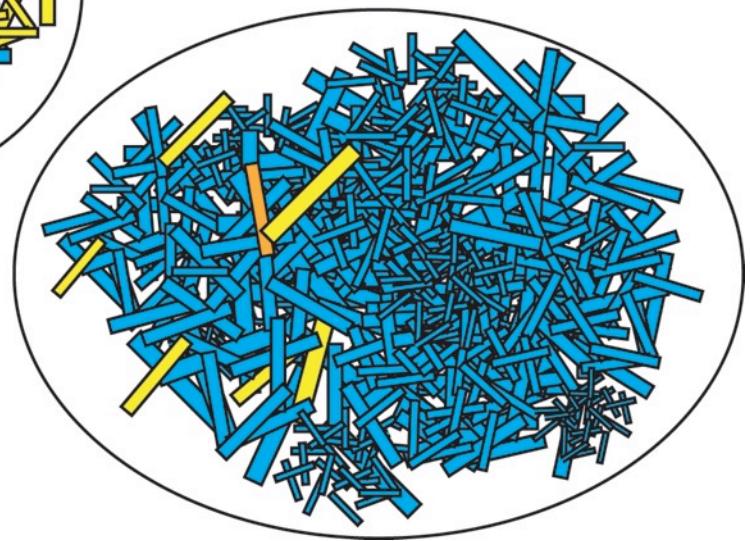

Pop A

Pop B

Pop C

Some of our research questions:

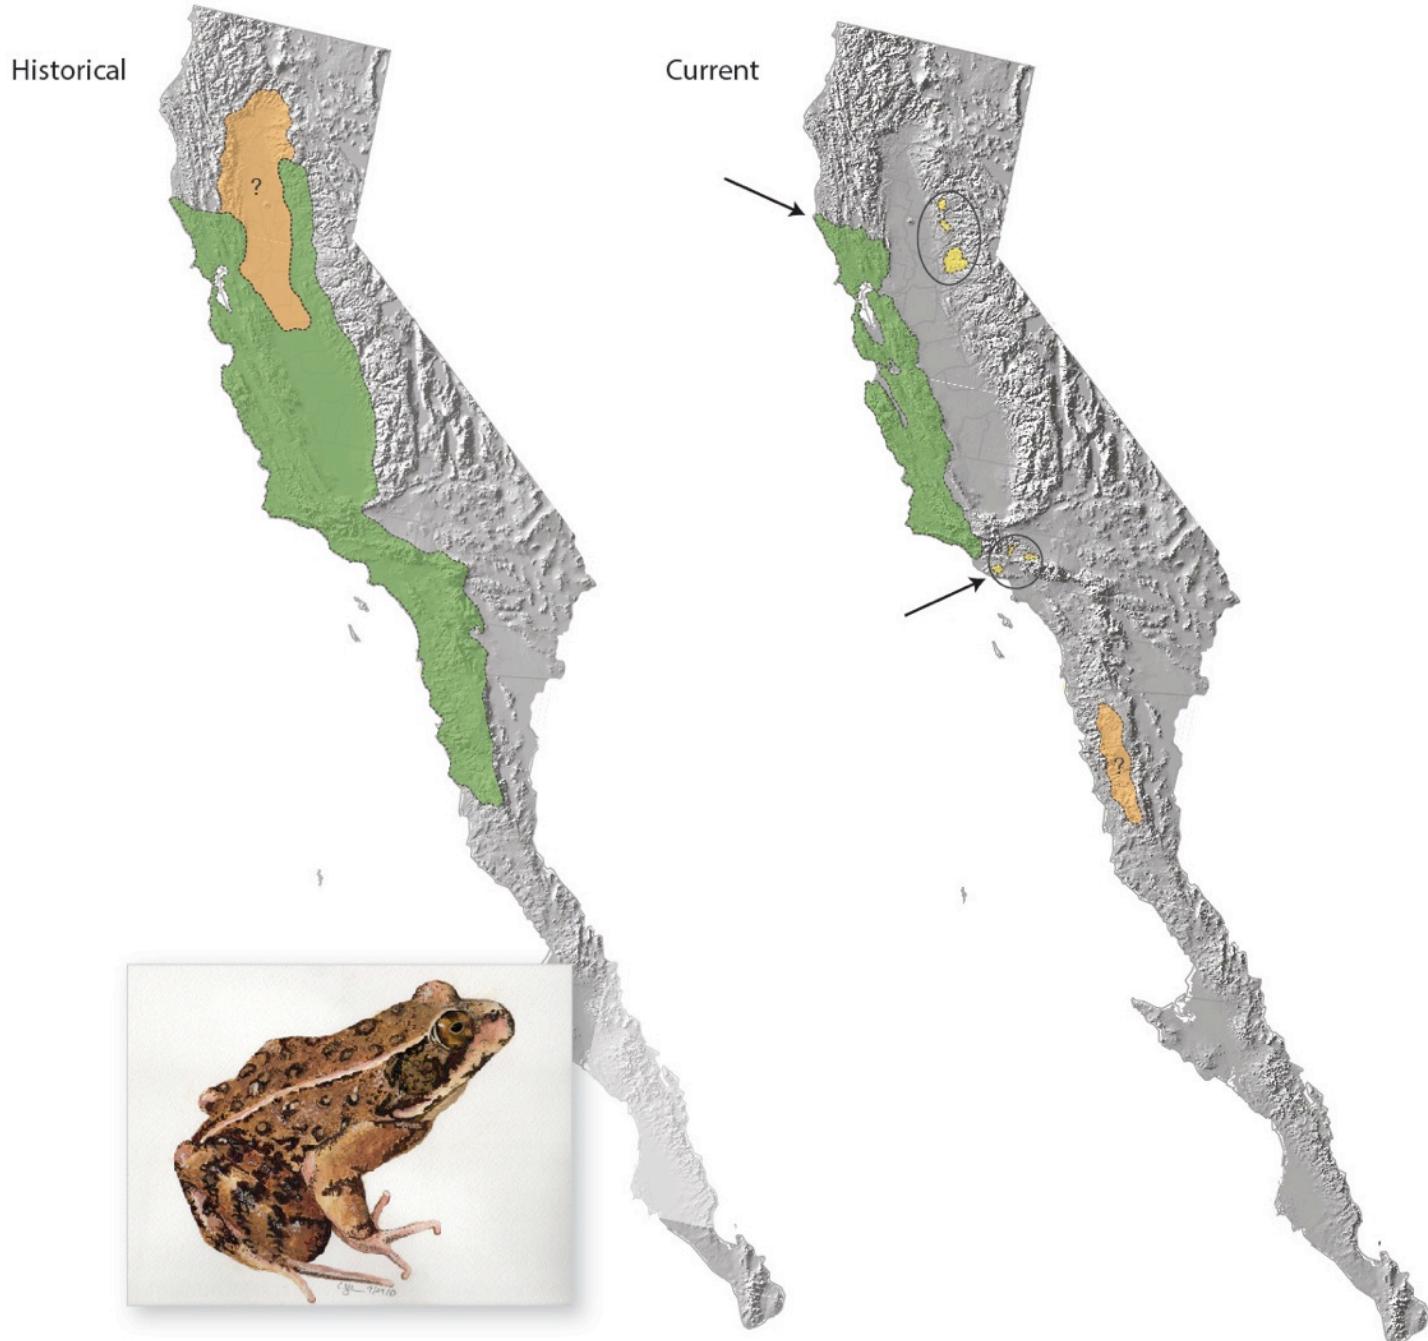

How are *R. draytonii* populations genetically structured across the landscape?

How does within-population genetic diversity change with respect to proximity to the range edge?

What factors determine the levels of within-population genetic diversity in California Red-legged frogs, particularly at the range edge?

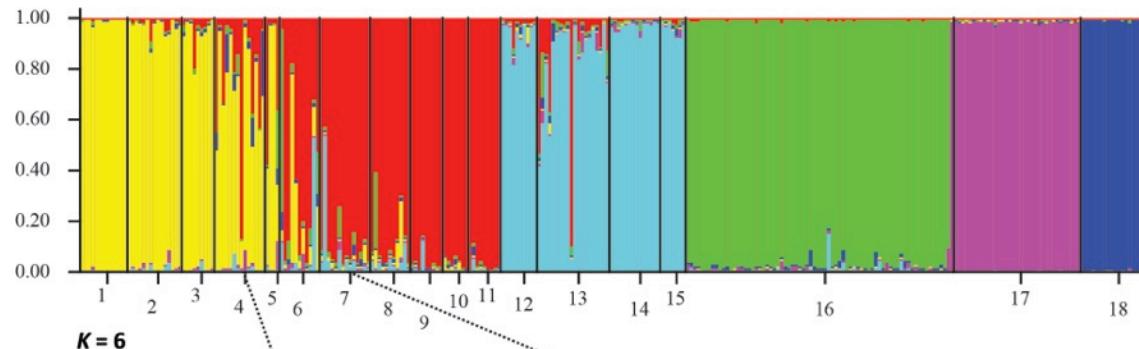

How can we identify suitable source populations for translocation to areas formerly occupied by *R. draytonii* in California?

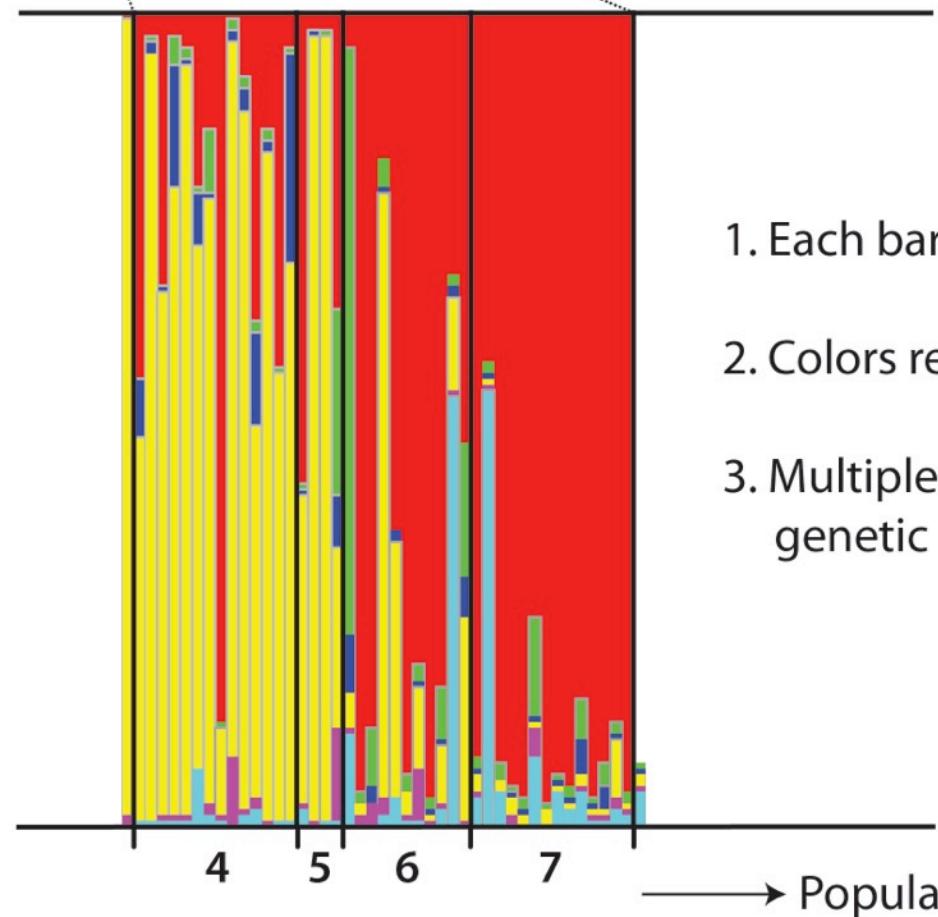

What types of data did we use?

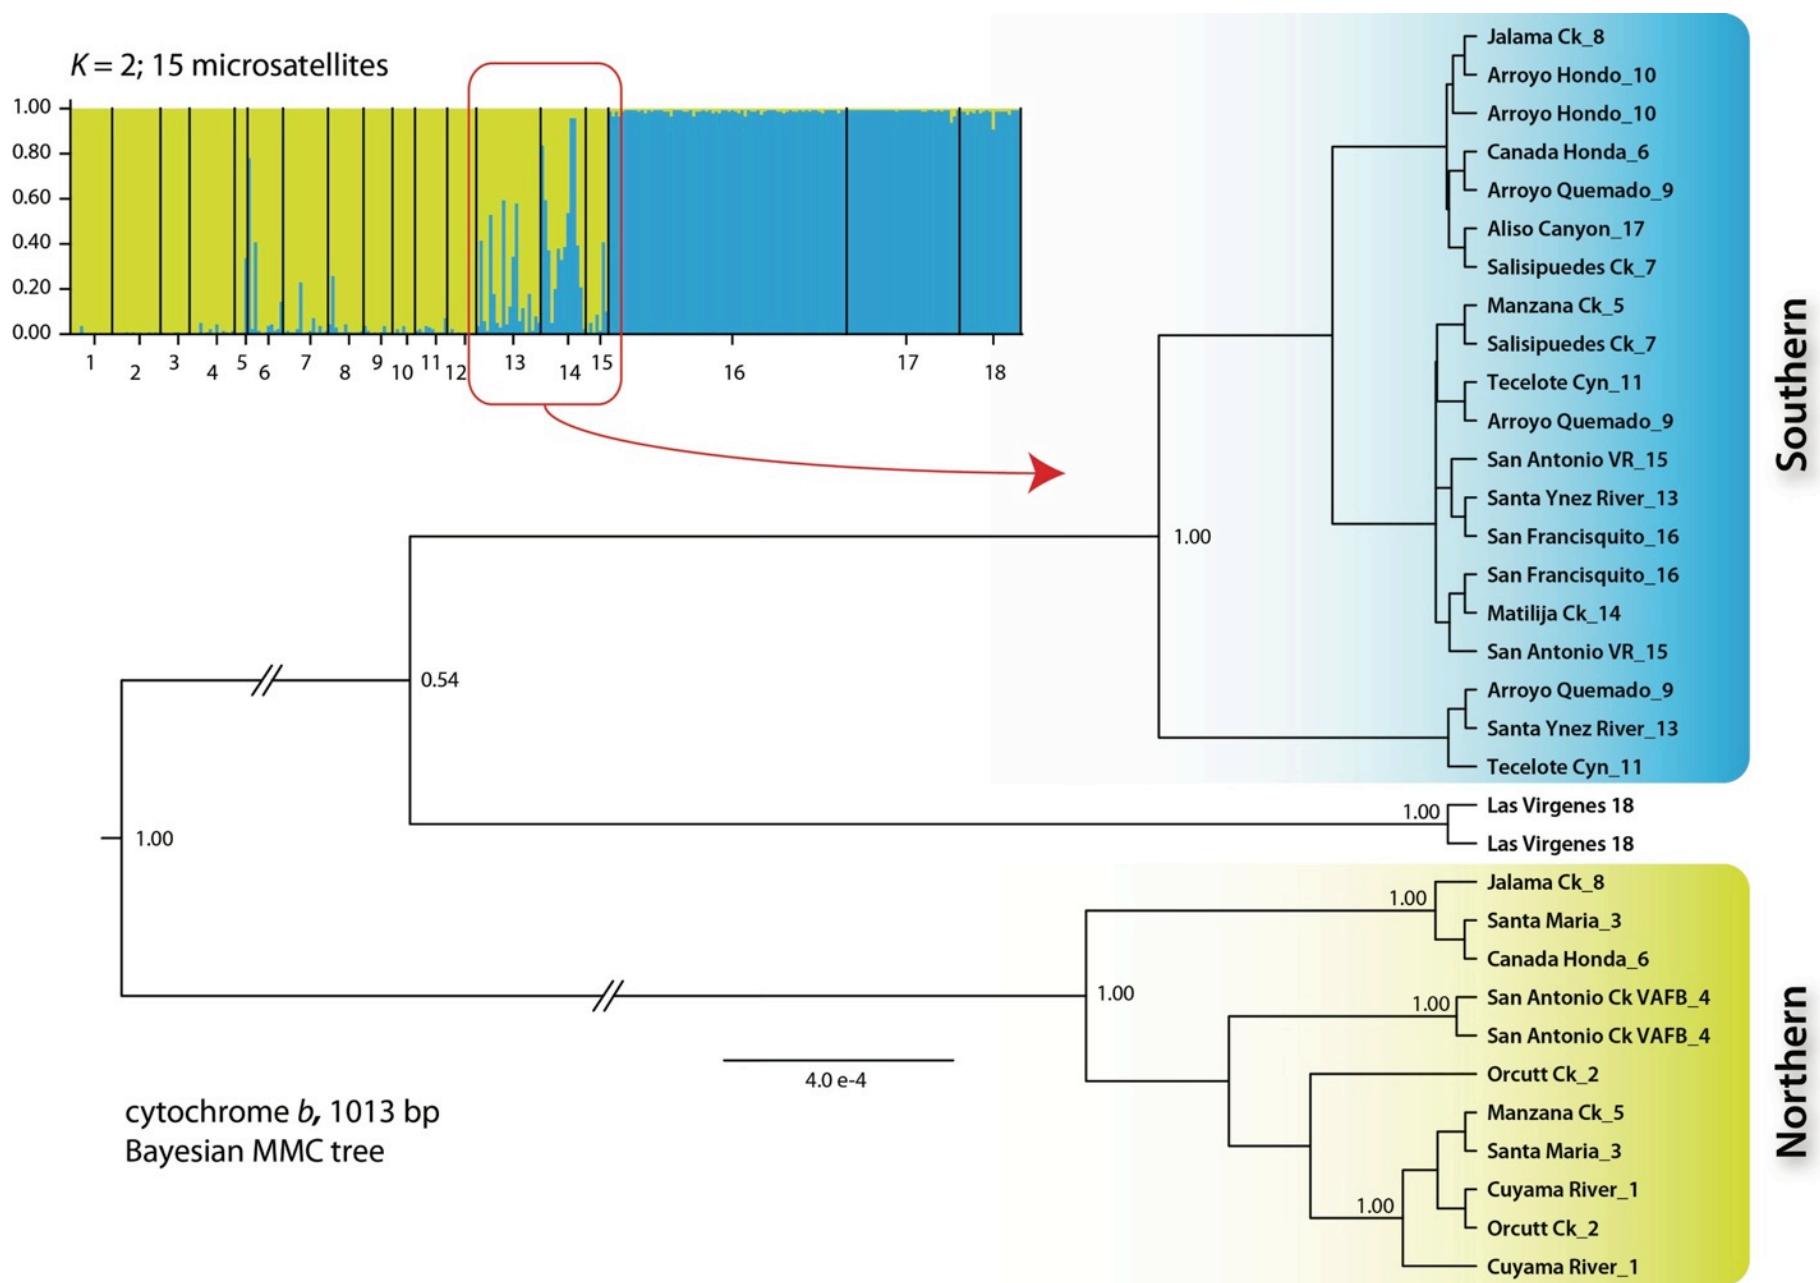

1. Mitochondrial DNA sequence data (1013 nucleotides for the *cyt b* gene)
 - Estimated a phylogenetic tree to assess the relationships of frogs from different sampling locations
 - Identify contact zones between evolutionarily divergent groups
2. Allele frequency data from 15 rapidly-evolving microsatellite loci
 - Identify natural genetic groups, or clusters based on the allele frequencies
 - Identify zones of admixture
 - Test for trends in genetic diversity with respect to proximity the range edge

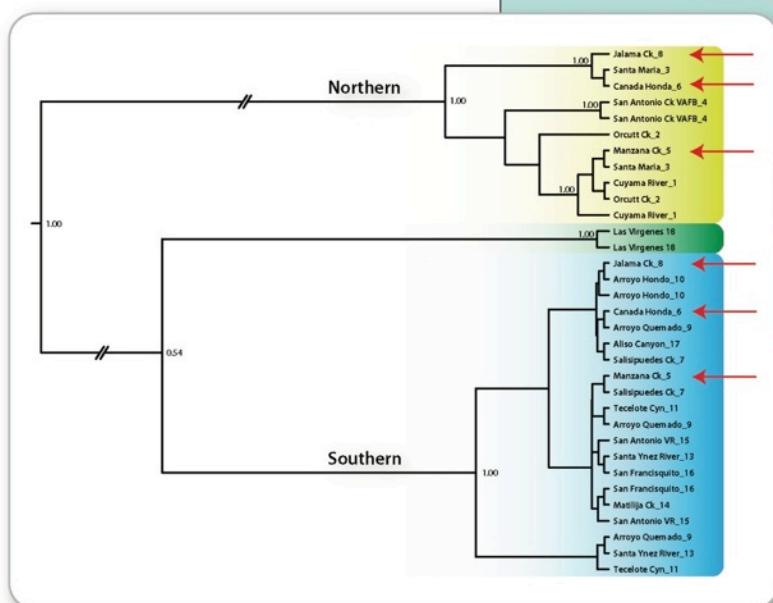

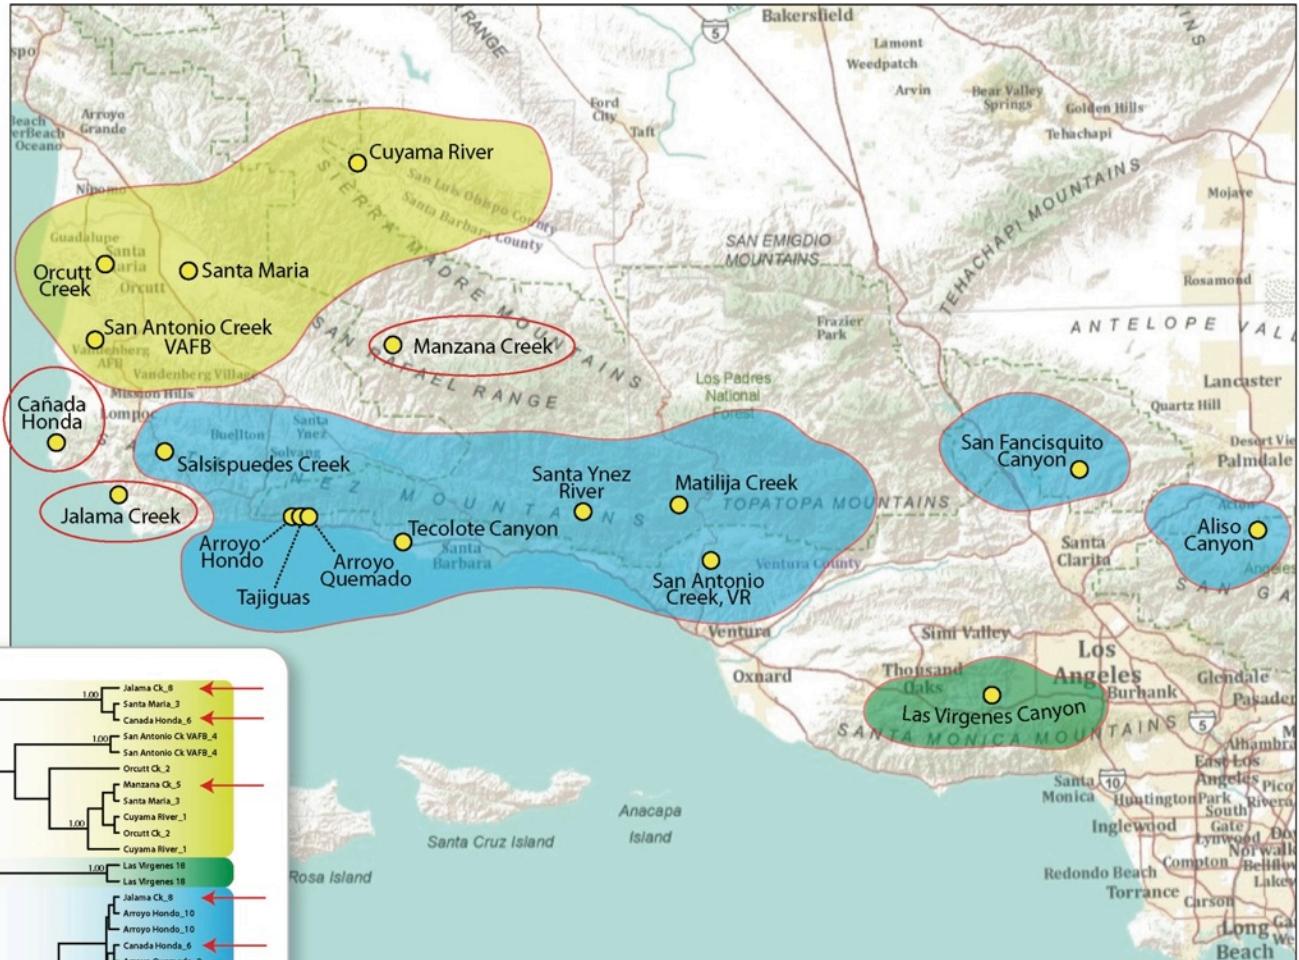

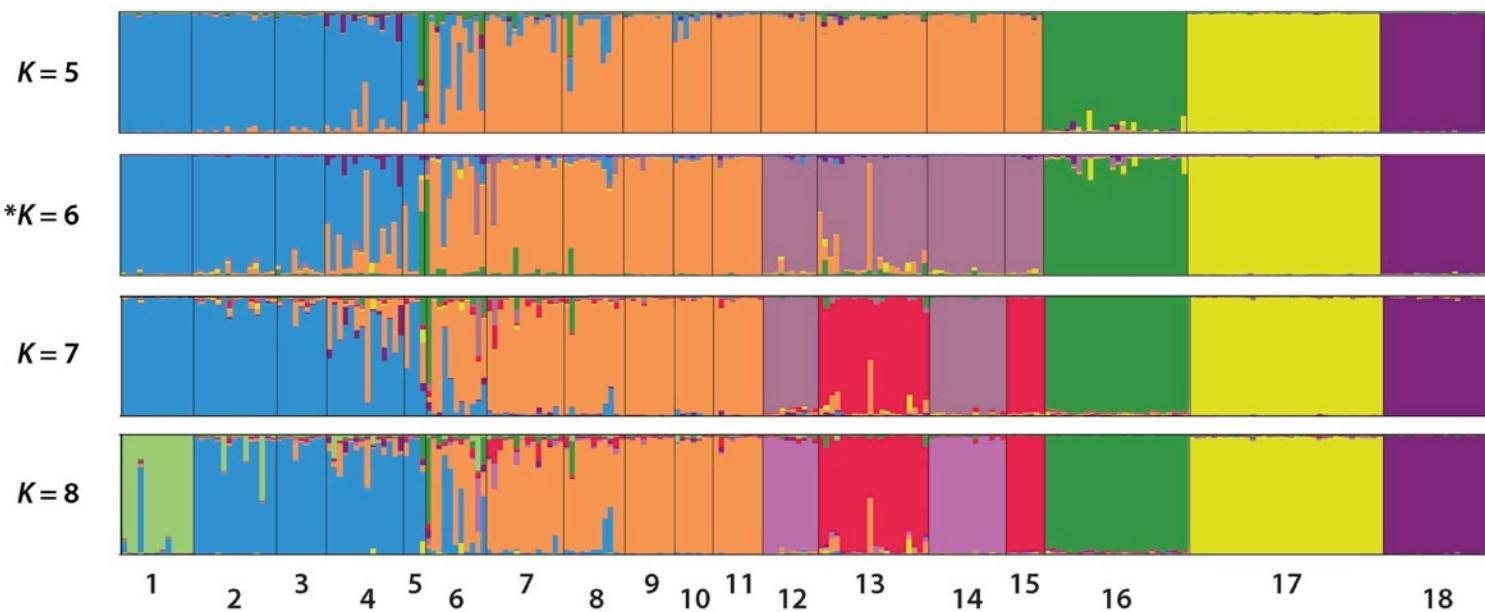

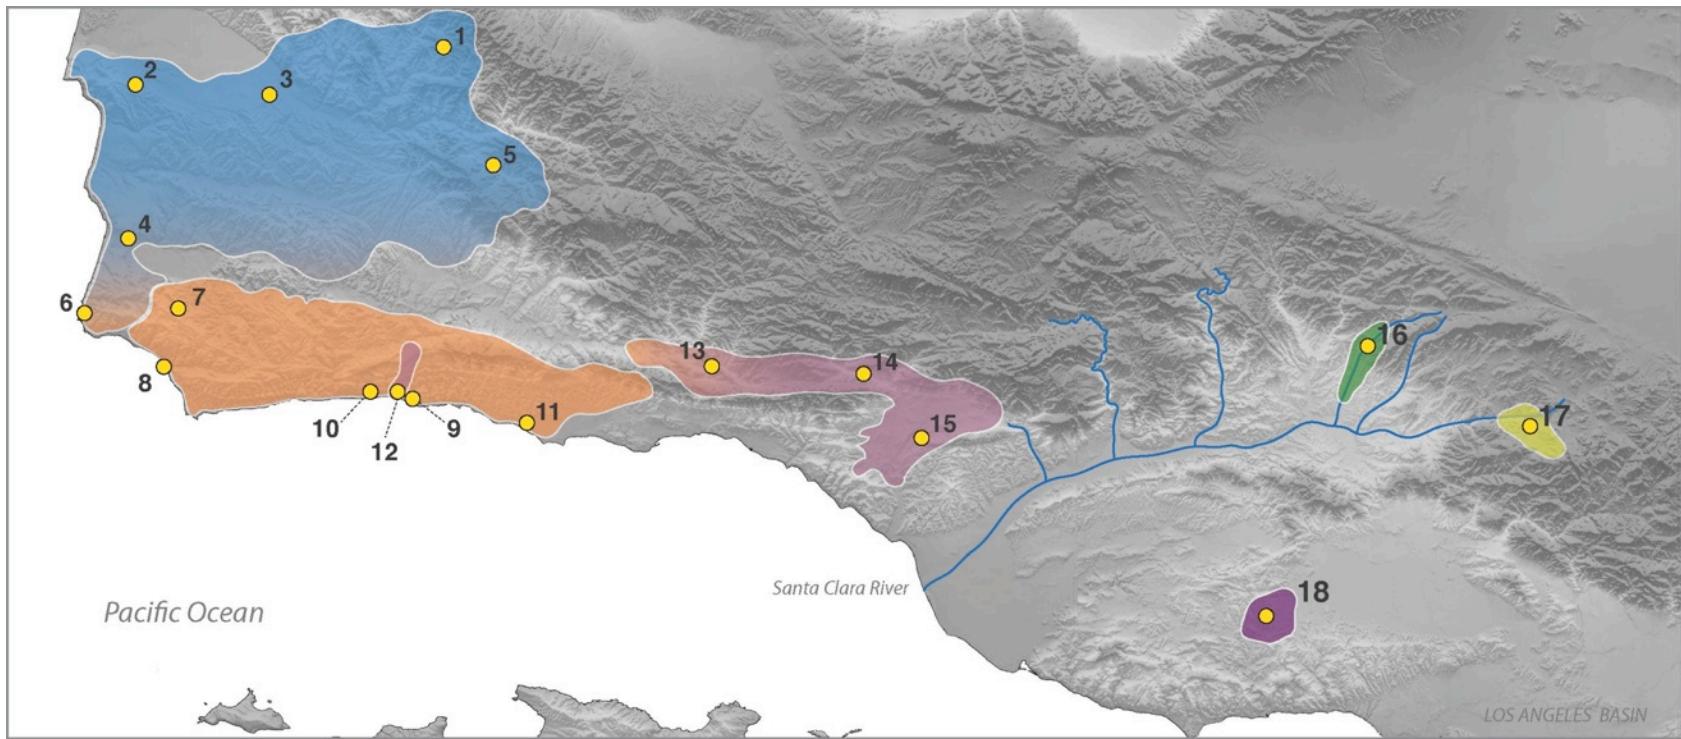

Assignment plot

1. Each bar in the histogram is an individual.
2. Colors represent genetic groups.
3. Multiple colors within a bar represent genetic admixture.

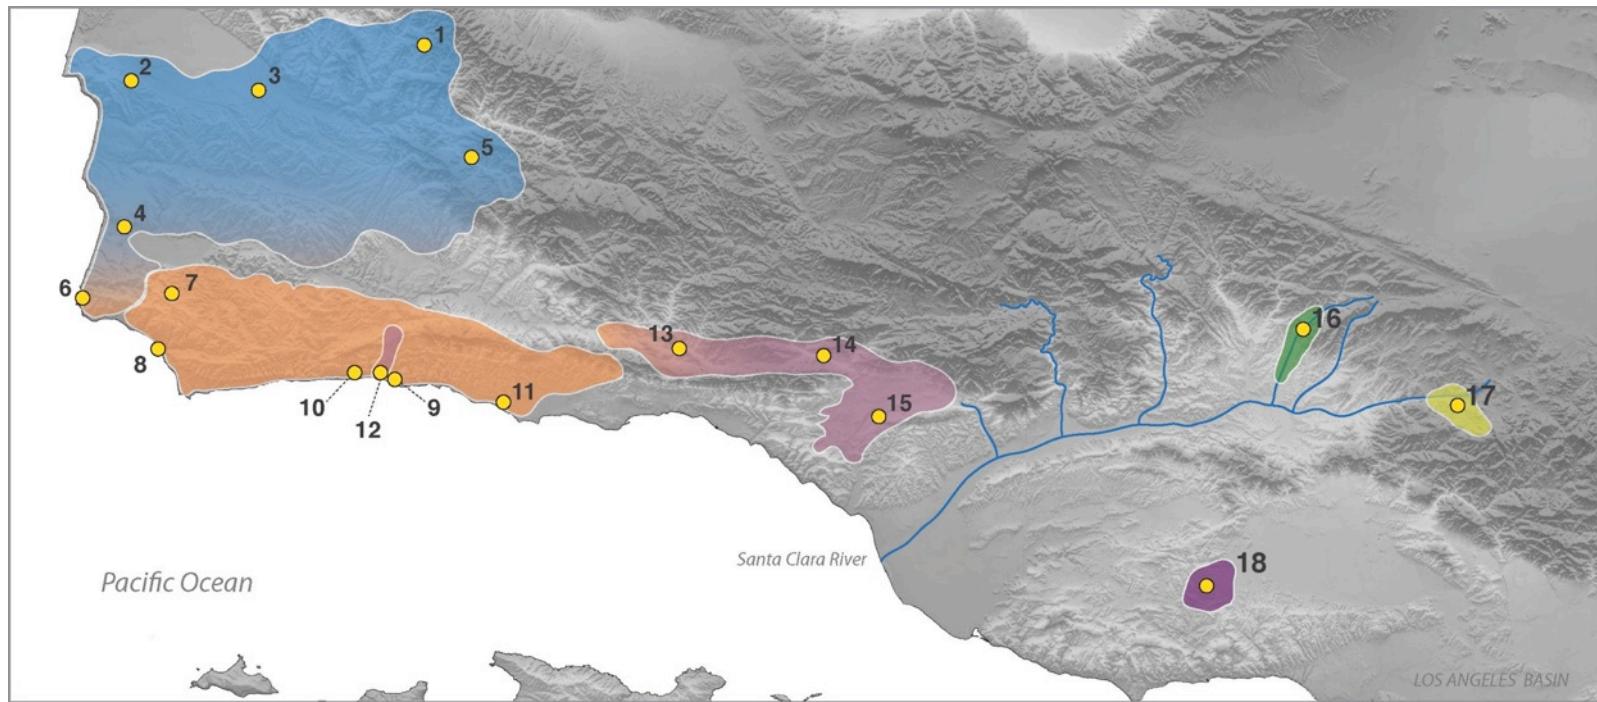

How can we measure genetic diversity?

Allelic richness A_r = number of alleles at locus for a given sample

Heterozygosity H = frequency of heterozygotes in a sample

- H ranges from zero (no heterozygosity) to nearly 1.0 (for a system with a large number of equally frequent alleles)
- H_O is the observed frequency of heterozygotes in a sample
- H_E is the expected heterozygosity under HWP

Relatedness = average pairwise measure of genetic similarity between individuals

What about effective population size?

It's true that most populations are large, but they don't necessarily act large...

This is because individuals vary in their ability to pass their genes on to the next generation.

So it is important to distinguish between

- The census (actual) population size N
- and the effective population size N_e (used for genetic calculations)

Anything that increases the variance among individuals in reproductive success will reduce N_e

Estimates of effective population size (N_e)

Sample	N_{loci}	$N_{e(\text{ABC})}$ (95%CI)	$N_{e(\text{LD})}$ (95%CI)
Santa Maria	15	28.01(23.24 - 51.98)	24.60 (20.8 – 29.95)
West Santa Ynez Mtn. 1	15	26.00 (23.74 - 29.95)	55.7 (42.9 – 75.6)
East Santa Ynez Mtn. 2	15	26.82 (21.63 - 36.56)	25.5 (19.9 – 33.4)
San Francisquito 2002	15	27.75 (24.82 - 34.65)	65.2 (25.9 - ∞)
San Francisquito 2005-06	15	25.66 (22.24 - 35.96)	46.1 (21.1 – 525.5)
San Francisquito 2009	15	20.27 (17.80 - 25.12)	11.1 (7.4 – 17.0)
Aliso Canyon	13	29.73 (25.14 - 44.79)	18.1 (8.4 – 47.1)
East Las Virgenes Canyon	12	15.93 (13.45 - 21.51)	12.3 (2.5 - ∞)

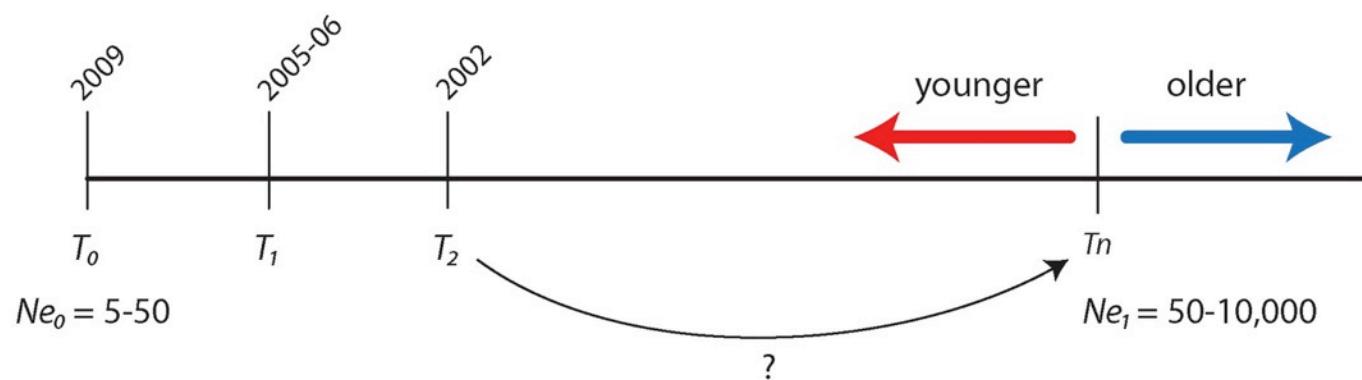

Why don't we see convincing evidence of a genetic decline following the fire-flood event, even though census surveys indicate that the population declined dramatically?

1. The population was bottlenecked to begin with, so only common alleles were present before the fire.
2. Frogs can and do survive the fires.
3. Long generation time causes genetic inertia, delaying the signature of a bottleneck in allele frequency data.

If bottleneck signatures cannot be traced to recent fires, then how long ago did the bottlenecks take place?

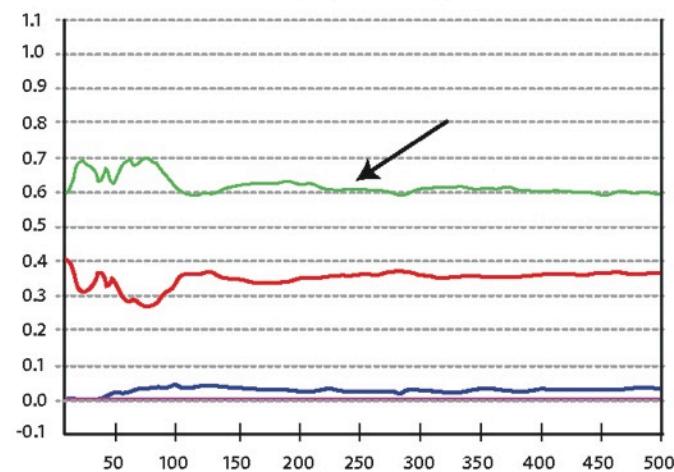

Approximate Bayesian Computation - DIYABC v1.0.4.46

1. Simulate datasets assuming different demographic scenarios:
 T_n number of generations ago (1-200), the effective population size $N_e 1$ (50-10000) greater than the current effective size $N_e 0$ (5-50)
2. Select simulated data sets (i.e scenarios) closest to the observed data set and estimate the posterior distribution of parameters through a linear regression procedure
3. Posterior predictive checks using the best-fit model to compare simulated parameter values to the observed data.

Current state of knowledge

1. Isolation, depauperate genetic diversity, lack of current gene flow, inability for new immigrants to enter range boundary populations, and susceptibility to fire/flood events suggests that peripheral populations in southern California are in an unstable condition and need to be managed.
2. Continued genetic monitoring for populations that have undergone known, severe declines would go a long way towards understanding the severity of bottlenecks and their implications for long term survival.
3. Spatial genetic data can and are being used to inform translocation efforts in manner consistent with the evolutionary dynamics of the species at the southern range boundary.
